

Tutorial Week 7: MDP

Guidelines

- You can discuss the content of the questions with your classmates.
- However, everyone should work on and be ready to present ALL the solutions.
- Your attendance is marked in the tutorial and participation noted to award class participation marks.

Problem 1: Online Search for Markov Decision Process

Consider an MDP where the state is described using M variables where each variable can take n values. The MDP has 2 actions and at each state each action can only lead to 2 possible next states.

- What is the size of the state space of this MDP? Can this MDP be efficiently solvable with value iteration as M grows?
- A search tree of depth D (number of actions from the root to any leaf is D) is constructed from an initial state s . What is the size of the search tree (the number of nodes and edges) as a function of M and D , in O -notation? Can online search be done efficiently as M grows if D is a fixed small constant?
- MCTS is used for solving this MDP. What is the size of the search tree if T trials of MTCS is performed up to a search depth of D , as a function of M , D and T in O -notation?
- Consider a search tree where the reward is zero everywhere except at the leaves. When a MCTS trial goes through a node, we say that an action at the node wins if the trial ends in a leaf with reward 1. Consider an MCTS simulation where a node has been visited 16 times and has two actions, A and B. Action A has won 2 out of 4 times whereas action B has won 8 out of 12 times. Which action will the MCTS algorithm chose given the exploration parameter c is set to 1? Give the values of π_{UCT} for the node (consider log base 2 in UCT bound).

Problem 2: Value Iteration

Consider the following 2 state, 2 action MDP with discount factor 0.9.

$P(s_1 s_1, a_1)$	$P(s_2 s_1, a_1)$	$P(s_1 s_2, a_1)$	$P(s_2 s_2, a_1)$
0.9	0.1	0	1

$P(s_1 s_1, a_2)$	$P(s_2 s_1, a_2)$	$P(s_1 s_2, a_2)$	$P(s_2 s_2, a_2)$
0.1	0.9	0	1

$R(s_1, a_1)$	$R(s_1, a_2)$	$R(s_2, a_1)$	$R(s_2, a_2)$
1	0	3	3

1. Assume a finite horizon problem with horizon 1 (only 1 action is to be taken). What is the utility or value function and the optimal action in each state?
2. Assume a finite horizon problem with horizon 2 (2 actions to be taken). What is the utility or value function and the optimal action in each state?
3. What is the optimal infinite horizon policy?

Problem 3: Bellman operator

[RN 17.6] Suppose that we view the Bellman update

$$U_{t+1}(s) \leftarrow R(s) + \gamma \max_{a \in A(s)} \sum_{s'} P(s'|s, a) U_t(s')$$

as an operator B that is applied simultaneously to update the utility of every state, that is,

$$U_{t+1} \leftarrow BU_t .$$

We claim that the Bellman operator B is a contraction.

1. Show that, for any function f and g ,

$$\left| \max_a f(a) - \max_a g(a) \right| \leq \max_a |f(a) - g(a)| .$$

2. Write out an expression for $|(BU_t - BU'_t)(s)|$ and then apply the result from part 1 to complete the proof that the Bellman operator B is a contraction.
-
